## 1 Introduction

This is a simulation study comparing various methods for imputation of missing covariate data in a survival analysis in which there are interactions between the predictor variables. We compare our new Random Forest method for MICE (Multivariate Imputation by Chained Equations) with other imputation methods and full data analysis. In our Random Forest method (RFcont), the conditional mean missing values are predicted using Random Forest and imputed values are drawn from Normal distributions centred on the predicted means [1].

We also perform a comparison with the methods recently published by Doove et al. [2]: `mice.impute.cart` (classification and regression trees in MICE) and `mice.impute.rf` (MICE using Random Forests).

## 2 Methods

We used the R packages **CALIBERrfimpute**, **survival**, **xtable**, **missForest** and **randomForest**. We created simulated survival datasets with two fully observed predictor variables ( $x_1$ ,  $x_2$ ) and a partially observed predictor ( $x_3$ ), which depends on  $x_1$ ,  $x_2$  and their interaction. They were generated as follows:

$x_1$  Standard normal distribution

$x_2$  Standard normal distribution, independent of  $x_1$

$x_3$  Derived from  $x_1$  and  $x_2$ :  $x_3 = 0.5(x_1 + x_2 - x_1 \cdot x_2) + e$  where  $e$  is normally distributed with mean 0 and variance 1.

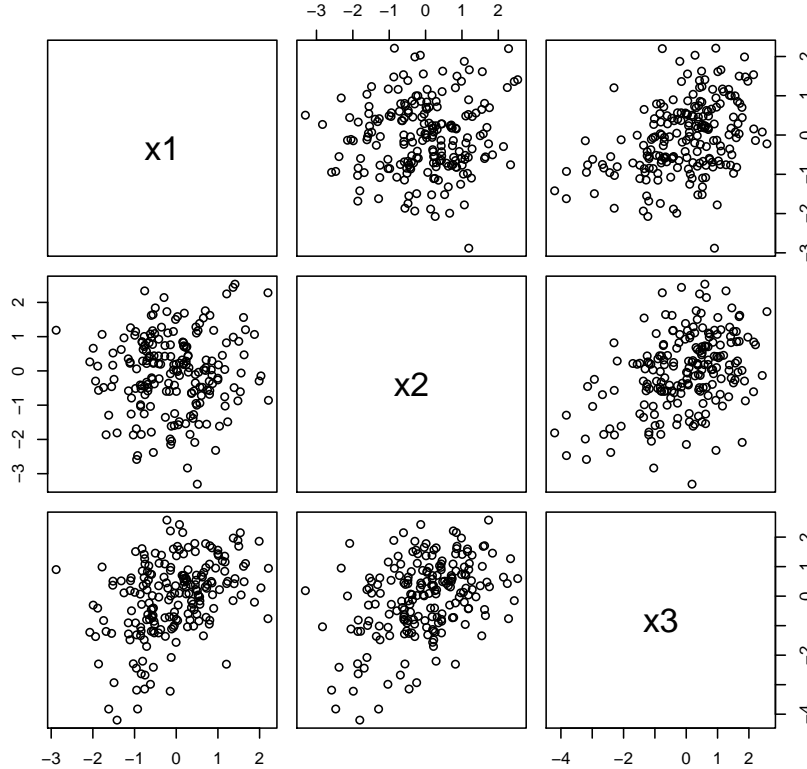

The equation for the log hazard of patient  $i$  was given by:

$$h_i = \beta_1 x_{1i} + \beta_2 x_{2i} + \beta_3 x_{3i} \quad (1)$$

where all the  $\beta$  coefficients were set to 0.5.

We used an exponential distribution to generate a survival time for each patient. We also generated an observation time for each patient, as a random draw from a uniform distribution bounded by zero and the 50<sup>th</sup> percentile of survival time. If the observation time was less than the survival time, the patient was considered as censored (event indicator 0, and the patient's follow-up ends on their censoring date), otherwise the event indicator was 1, with follow-up ending on the date of event.

### Associations between predictor variables in a sample dataset

Linear regression model relating  $x_3$  to  $x_1$  and  $x_2$ :

```
> summary(lm(x3 ~ x1*x2, data = mydata))
```

Call:

```
lm(formula = x3 ~ x1 * x2, data = mydata)
```

Residuals:

	Min	1Q	Median	3Q	Max
	-3.7452	-0.6819	-0.0041	0.6867	4.0478

Coefficients:

	Estimate	Std. Error	t value	Pr(> t )
(Intercept)	-0.008003	0.007081	-1.13	0.258
x1	0.509079	0.007058	72.12	<2e-16 ***
x2	0.506407	0.007048	71.85	<2e-16 ***
x1:x2	-0.500635	0.007089	-70.62	<2e-16 ***

---

Signif. codes: 0 '\*\*\*' 0.001 '\*\*' 0.01 '\*' 0.05 '.' 0.1 ' ' 1

Residual standard error: 1.001 on 19996 degrees of freedom

Multiple R-squared: 0.4271, Adjusted R-squared: 0.427

F-statistic: 4969 on 3 and 19996 DF, p-value: < 2.2e-16

### Association of predictor variables $x_1$ and $x_3$

All true log hazard ratios were assumed to be 0.5, with hazard ratios = 1.65. We checked that the hazard ratios in the simulated data were as expected for a large sample:

```
> # Cox proportional hazards analysis
> myformula <- as.formula(Surv(time, event) ~ x1 + x2 + x3)
```

```

> # Analysis with 10,000 simulated patients (or more
> # if the variable REFERENCE_SAMPLESIZE exists)
> if (!exists('REFERENCE_SAMPLESIZE')){
+   REFERENCE_SAMPLESIZE <- 10000
+ }
> # Use parallel processing, if available, to create
> # datasets more quickly.
> if ('parallel' %in% loadedNamespaces() &&
+   !is.null(getOption('mc.cores')) &&
+   .Platform$OS.type == 'unix'){
+   REFERENCE_SAMPLESIZE <- REFERENCE_SAMPLESIZE %/%
+     getOption('mc.cores')
+   simdata <- parallel::mclapply(1:getOption('mc.cores'),
+     function(x) makeSurv(REFERENCE_SAMPLESIZE))
+   simdata <- do.call('rbind', simdata)
+ } else {
+   simdata <- makeSurv(REFERENCE_SAMPLESIZE)
+ }
> summary(coxph(myformula, data = simdata))

```

Call:

```
coxph(formula = myformula, data = simdata)
```

n= 9990, number of events= 3022

	coef	exp(coef)	se(coef)	z	Pr(> z )
x1	0.51304	1.67037	0.01949	26.32	<2e-16 ***
x2	0.49204	1.63566	0.01919	25.65	<2e-16 ***
x3	0.50425	1.65574	0.01701	29.64	<2e-16 ***

---

	exp(coef)	exp(-coef)	lower .95	upper .95
x1	1.670	0.5987	1.608	1.735
x2	1.636	0.6114	1.575	1.698
x3	1.656	0.6040	1.601	1.712

Concordance= 0.763 (se = 0.006 )

Rsquare= 0.246 (max possible= 0.995 )

Likelihood ratio test= 2824 on 3 df, p=0

Wald test = 2410 on 3 df, p=0

Score (logrank) test = 2373 on 3 df, p=0

We created datasets containing 2000 simulated patients. For each dataset, we first analysed the complete dataset with no values missing, then artificially created missingness in variable  $x_3$ , imputed the missing values using various methods, and analysed the imputed datasets. We combined parameter estimates from multiply imputed datasets using Rubin's rules.

## 2.1 Missingness mechanism

Missingness was imposed in  $x_3$  dependent on  $x_1$ ,  $x_2$ , the event indicator and the marginal Nelson-Aalen cumulative hazard, using a logistic regression model. The linear predictors

were offset by an amount chosen to make the overall proportion of each variable missing approximately 0.2, i.e.:

$$P(\text{miss})_i = \frac{\exp(lp_i + \text{offset})}{1 + \exp(lp_i + \text{offset})} \quad (2)$$

$$lp_i = 0.1x_{1i} + 0.1x_{2i} + 0.1 \times \text{cumhaz}_i + 0.1 \times \text{event}_i \quad (3)$$

where ‘event’ is the event indicator and ‘cumhaz’ is the marginal Nelson-Aalen cumulative hazard.

We analysed the datasets with missing data using different methods of multiple imputation. We calculated the marginal Nelson-Aalen cumulative hazard and included it in all imputation models, along with the event indicator and follow-up time.

```
> # Setting analysis parameters: To analyse more than 3 samples,
> # set N to the desired number before running this program
> if (!exists('N')){
+   N <- 3
+ }
> # Number of imputations (set to at least 10 when
> # running an actual simulation)
> if (!exists('NIMPS')){
+   NIMPS <- 3
+ }
> # Use parallel processing if the 'parallel' package is loaded
> if ('parallel' %in% loadedNamespaces() &&
+   .Platform$OS.type == 'unix'){
+   cat('Using parallel processing\n')
+   results <- parallel::mclapply(1:N, doanalysis)
+ } else {
+   results <- lapply(1:N, doanalysis)
+ }
```

Using parallel processing

We used the following methods of multiple imputation. The number of imputations was 10. In each case, the imputation model for  $x_3$  contained  $x_1$ ,  $x_2$ , the event indicator and the marginal Nelson-Aalen cumulative hazard:

**missForest** – from the missForest package, which completes a dataset in an iterative way using Random Forest prediction. It was run with maximum 10 iterations (default) and 100 trees per forest (default).

**CART MICE** – Classification and regression tree MICE method from the mice package (mice.impute.cart).

**RF MICE (Doove)** – Random Forest MICE method from Doove et al. [2], which is available as function mice.impute.rf in the mice package, with 10 or 100 trees.

**RFcont MICE** – Random Forest MICE method from the CALIBERrfimpute package with 5, 10, 20 or 100 trees.

**Parametric MICE** – normal-based linear regression with default settings, in which the imputation model for  $x_3$  is of the form:

$$x_3 = \beta_0 + \beta_1.x_1 + \beta_2.x_2 + \beta_3.\text{event} + \beta_4.\text{cumhaz} + e$$

where  $e$  is the residual variance.

We analysed 1000 samples. We calculated the following for each method and each parameter:

- Bias of log hazard ratio
- Standard error of bias (Monte Carlo error)
- Mean square error
- Standard deviation of estimated log hazard ratio
- Mean length of 95% confidence intervals
- Coverage of 95% confidence intervals (proportion containing the true log hazard ratio)

### 3 Results

All the true log hazard ratios were set at 0.5.

#### 3.1 Fully observed variables

Log hazard ratio for the continuous fully observed variable  $x_1$ :

RFcont MICE 10	-0.00601	0.00127	0.00165	0.0402	0.169	0.961
RFcont MICE 20	0.00403	0.00129	0.00169	0.0409	0.167	0.959
RFcont MICE 100	0.0115	0.00131	0.00185	0.0414	0.167	0.952
Parametric MICE	-0.056	0.00124	0.00466	0.0391	0.178	0.78

The following graph shows the bias for RFcont MICE methods by number of trees (bias estimated from 1000 simulations; the lines denote 95% confidence intervals):

## 3.3 Pairwise comparisons between methods

### 3.3.1 Comparison of bias

Difference between absolute bias (negative means that the first method is less biased). P values from paired sample t tests. Significance level: \*  $P < 0.05$ , \*\*  $P < 0.01$ , \*\*\*  $P < 0.001$ .

Coefficient	RFcont MICE 10 vs parametric MICE	RFcont MICE 100 vs parametric MICE	RFcont MICE 10 vs RFcont MICE 100
x1	-0.0256 ***	-0.0225 ***	-0.00301 ***
x2	-0.0253 ***	-0.0223 ***	-0.00296 ***
x3	-0.05 ***	-0.0445 ***	-0.00545 *

Coefficient	RF Doove MICE 10 vs RFcont MICE 10	RF Doove MICE 10 vs CART MICE	RF Doove MICE 10 vs RF Doove MICE 100
x1	0.000035	0.00159 ***	-0.00117
x2	0.000208	0.00139 ***	0.00198
x3	0.000281	-0.00371 ***	-0.0027 ***

### 3.3.2 Comparison of precision

Ratio of variance of estimates (less than 1 means that the first method is more precise). P values from F test. Significance level: \* P <0.05, \*\* P <0.01, \*\*\* P <0.001.

Coefficient	RFcont MICE 10 vs parametric MICE	RFcont MICE 100 vs parametric MICE	RFcont MICE 10 vs RFcont MICE 100
x1	0.934	0.938	0.996
x2	0.921	0.923	0.998
x3	1.06	1.12	0.942

Coefficient	RF Doove MICE 10 vs RFcont MICE 10	RF Doove MICE 10 vs CART MICE	RF Doove MICE 10 vs RF Doove MICE 100
x1	1	0.968	1.04
x2	0.999	0.95	1.04
x3	1.01	0.878 *	1.08

### 3.3.3 Comparison of confidence interval length

Ratio of mean length of 95% confidence intervals (less than 1 means that the first method produces smaller confidence intervals). P values from paired sample t test. Significance level: \* P <0.05, \*\* P <0.01, \*\*\* P <0.001.

Coefficient	RFcont MICE 10 vs parametric MICE	RFcont MICE 100 vs parametric MICE	RFcont MICE 10 vs RFcont MICE 100
x1	0.9876 ***	0.9825 ***	1.005 ***

x3	0.9521 ***	0.9383 ***	1.015 ***

Coefficient	RF Doove MICE 10 vs RFcont MICE 10	RF Doove MICE 10 vs CART MICE	RF Doove MICE 10 vs RF Doove MICE 100
x1	1	1.013 ***	1.004 ***
x2	1	1.013 ***	1.005 ***
x3	0.9992	1.053 ***	1.02 ***

### 3.3.4 Comparison of confidence interval coverage

Difference between percentage coverage of 95% confidence intervals (positive means that the first method has greater coverage). P values for pairwise comparisons by McNemar's test. Significance level: \* P <0.05, \*\* P <0.01, \*\*\* P <0.001.

Coefficient	RFcont MICE 10 vs parametric MICE	RFcont MICE 100 vs parametric MICE	RFcont MICE 10 vs RFcont MICE 100
x1	5.8 ***	5.2 ***	0.6
x2	6.0 ***	5.9 ***	0.1
x3	18.1 ***	17.2 ***	0.9

Coefficient	RF Doove MICE 10 vs RFcont MICE 10	RF Doove MICE 10 vs CART MICE	RF Doove MICE 10 vs RF Doove MICE 100
x1	-0.3	0.3	-0.6
x2	0.2	1.5 **	-0.5
x3	-0.1	2.5 ***	-0.3

## 4 Discussion

In this simulation, parametric MICE using the default settings yielded a biased estimate for the coefficient for the partially observed variable  $x_3$ . This is because the interaction between  $x_1$  and  $x_2$  was not included in the imputation models. The estimate using the CART or Random Forest MICE methods were less biased, more precise and had shorter confidence intervals with greater coverage. Omissions of interactions between predictors can potentially result in bias using parametric MICE even if, as in this case, the interaction is not present in the substantive model.

### 4.1 CART versus Random Forest MICE

CART MICE produced estimates for the  $x_3$  coefficient that were less precise than the Random Forest MICE methods, and coverage of 95% confidence intervals was only 93%.

### 4.2 Comparison of Random Forest MICE methods

Coefficients estimated after imputation using CART or Random Forest MICE methods were slightly biased. The bias was statistically significant but small in magnitude. Using RFcont MICE, the  $x_3$  coefficient was biased towards the null with 5 or 10 trees and biased away from the null with 20 or more trees; bias was minimised using 10 or 20 trees.

Confidence intervals estimated using Doove's Random Forest MICE method were slightly shorter than those obtained using RFcont MICE but coverage was >95% with both methods.

Doove's method was slightly slower than RFcont and the computation time for each Random Forest method was proportional to the number of trees.

### 4.3 missForest

Parameters estimated after imputation using missForest were biased and the coverage of 95% confidence intervals was less than 95%. Failure to draw from the correct conditional distribution leads to bias and underestimation of the uncertainty when statistical models are fitted to imputed data.

### 4.4 Implications for further research

This simulation demonstrates a situation in which Random Forest MICE methods have an advantage over parametric MICE. Both Doove's method (RF) and our method (RFcont) performed well, and on some performance measures Doove's method was superior.

It would be useful to compare these methods in simulations based on real datasets.

## 5 Appendix: R code

### 5.1 R functions

This R code needs to be run in order to load the necessary functions before running the script (Section 5.2).

#### 5.1.1 Data generating functions

```
makeSurv <- function(n = 2000, loghr = kLogHR){
  # Creates a survival cohort of n patients. Assumes that censoring is
  # independent of all other variables

  # x1 and x2 are random normal variables
  data <- data.frame(x1 = rnorm(n), x2 = rnorm(n))

  # Create the x3 variable
  data$x3 <- 0.5 * (data$x1 + data$x2 - data$x1 * data$x2) + rnorm(n)

  # Underlying log hazard ratio for all variables is the same
  data$y <- with(data, loghr * (x1 + x2 + x3))
  data$survtime <- rexp(n, exp(data$y))

  # Censoring - assume uniform distribution of observation times
  # up to a maximum
  obstime <- runif(nrow(data), min = 0,
    max = quantile(data$survtime, 0.5))
  data$event <- as.integer(data$survtime <= obstime)
  data$time <- pmin(data$survtime, obstime)

  # Observed marginal cumulative hazard for imputation models
  data$cumhaz <- nelsonaalen(data, time, event)

  # True log hazard and survival time are not seen in the data
  # so remove them
  data$y <- NULL
  data$survtime <- NULL

  return(data)
}

makeMarSurv <- function(data, pmissing = kPmiss){
  # Introduces missing data dependent on event indicator
  # and cumulative hazard and x1 and x2

  logistic <- function(x){
    exp(x) / (1 + exp(x))
  }

  predictions <- function(lp, n){
    # uses the vector of linear predictions (lp) from a logistic model
    # and the expected number of positive responses (n) to generate
    # a set of predictions by modifying the baseline
  }
}
```

```

trialn <- function(lptrial){
  sum(logistic(lptrial))
}
stepsize <- 32
lptrial <- lp
while(abs(trialn(lptrial) - n) > 1){
  if (trialn(lptrial) > n){
    # trialn bigger than required
    lptrial <- lptrial - stepsize
  } else {
    lptrial <- lptrial + stepsize
  }
  stepsize <- stepsize / 2
}
# Generate predictions from binomial distribution
as.logical(rbinom(logical(length(lp)), 1, logistic(lptrial)))
}
data$x3[predictions(0.1 * data$x1 + 0.1 * data$x2 +
  0.1 * data$cumhaz + 0.1 * data$event, nrow(data) * pmissing)] <- NA
return(data)
}

```

### 5.1.2 Functions to analyse data

```

coxfull <- function(data){
  # Full data analysis
  coefs <- summary(coxph(myformula, data = data))$coef
  # return a vector of coefficients (est), upper and lower 95% limits
  confint <- cbind(coefs[, 'coef'] - qnorm(0.975) * coefs[, 'se(coef)'],
    coefs[, 'coef'] + qnorm(0.975) * coefs[, 'se(coef)'])
  out <- cbind(coefs[, 'coef'], confint,
    kLogHR >= confint[,1] & kLogHR <= confint[,2])
  colnames(out) <- c('est', 'lo 95', 'hi 95', 'cover')
  out
}

coximpute <- function(imputed_datasets){
  # Analyses a list of imputed datasets
  docoxmodel <- function(data){
    coxph(myformula, data=data)
  }
  mirafits <- as.mira(lapply(imputed_datasets, docoxmodel))
  out <- summary(pool(mirafits))
  out <- cbind(out, kLogHR >= out[, 'lo 95'] & kLogHR <= out[, 'hi 95'])
  # Whether this confidence interval contains the true hazard ratio
  colnames(out)[length(colnames(out))] <- 'cover'
  out
}

domissf <- function(missdata, reps = NIMPS){
  # Imputation by missForest
  out <- list()
  for (i in 1:reps){

```

```

invisible(capture.output(
  out[[i]] <- missForest(missdata)$ximp))
}
out
}
